

AUTOMOTIVE CURRENT TRANSDUCER OPEN LOOP TECHNOLOGY

HAM 250-S04

Introduction

The HAM family is for the electronic measurement of DC, AC or pulsed currents in automotive applications with galvanic separation between the primary circuit (high power) and the secondary circuit (electronic circuit).

The HAM family gives you the choice of having different current measuring ranges in the same housing (from ± 100 A up to ± 300 A).

The HAM 250-S04 is designed for high frequency applications current with high primary current ripple.

Features

- Open Loop transducer using the Hall effect
- High voltage application
- Unipolar +5 V DC power supply
- Primary current measuring range up to ± 250 A
- Maximum RMS primary admissible current: defined by busbar to have $T < +150$ °C
- Operating temperature range: -40 °C $< T < +125$ °C
- Output voltage: full ratio-metric (in sensitivity and offset)
- Ferrite material magnetic core allowing high frequency primary current ripple with low self-heating.

Advantages

- Excellent accuracy
- Very good linearity
- Very low thermal offset drift
- Very low thermal sensitivity drift
- High frequency bandwidth
- Non insertion losses
- Very fast response time.

Automotive applications

- DC / DC converter for fuel cell, for xEV or PHEV
- DC/AC Inverter.

Principle of HAM 250-S04 family

The open loop transducers uses a Hall effect integrated circuit. The magnetic flux density B , contributing to the rise of the Hall voltage, is generated by the primary current I_p to be measured.

The current to be measured I_p is supplied by a current source i.e. battery or generator (Figure 1).

Within the linear region of the hysteresis cycle, B is proportional to:

$$B(I_p) = a \times I_p$$

The Hall voltage is thus expressed by:

$$V_H = (c_H / d) \times I_H \times a \times I_p$$

Except for I_p , all terms of this equation are constant. Therefore:

$$V_H = b \times I_p$$

a constant

b constant

c_H Hall coefficient

d thickness of the Hall plate

I_H current across the Hall plates

The measurement signal V_H amplified to supply the user output voltage or current.

Fig. 1: Principle of the open loop transducer.

Dimensions (in mm)

Mechanical characteristics

- Plastic case PBT GF 30 % (color black)
- Magnetic core Ferrite
- Mass see drawing
- Pins see drawing
- IP level IP2.

PERFORMANCES PARAMETERS DEFINITIONS

Primary current definition:

Definition of typical, minimum and maximum values:

Minimum and maximum values for specified limiting and safety conditions have to be understood as such as values shown in "typical" graphs. On the other hand, measured values are part of a statistical distribution that can be specified by an interval with upper and lower limits and a probability for measured values to lie within this interval. Unless otherwise stated (e.g. "100 % tested"), the LEM definition for such intervals designated with "min" and "max" is that the probability for values of samples to lie in this interval is 99.73 %. For a normal (Gaussian) distribution, this corresponds to an interval between -3 sigma and $+3$ sigma. If "typical" values are not obviously mean or average values, those values are defined to delimit intervals with a probability of 68.27 %, corresponding to an interval between $-\text{sigma}$ and $+\text{sigma}$ for a normal distribution. Typical, minimum and maximum values are determined during the initial characterization of a product.

Output noise voltage:

The output voltage noise is the result of the noise floor of the Hall elements and the linear amplifier.

Magnetic offset:

The magnetic offset is the consequence of an any current on the primary side. It's defined after a stated excursion of primary current.

Linearity:

The maximum positive or negative discrepancy with a reference straight line $V_{out} = f(I_p)$.

Unit: linearity (%) expressed with full scale of I_{pN} .

Response time (delay time) t_r :

The time between the primary current signal (I_{pN}) and the output signal reach at 90 % of its final value.

Sensitivity:

The transducer's sensitivity G is the slope of the straight line

$V_{out} = f(I_p)$, it must establish the relation:

$$V_{out}(I_p) = U_C/5 (G \times I_p + V_O)$$

Offset with temperature:

The error of the offset in the operating temperature is the variation of the offset in the temperature considered with the initial offset at 25 °C.

The offset variation I_{OT} is a maximum variation the offset in the temperature range:

$$I_{OT} = I_{OE \max} - I_{OE \min}$$

The offset drift TCI_{OEAV} is the I_{OT} value divided by the temperature range.

Sensitivity with temperature:

The error of the sensitivity in the operating temperature is the relative variation of sensitivity with the temperature considered with the initial offset at 25 °C.

The sensitivity variation G_T is the maximum variation (in ppm or %) of the sensitivity in the temperature range:

$$G_T = (\text{Sensitivity max} - \text{Sensitivity min}) / \text{Sensitivity at } 25^\circ\text{C}.$$

The sensitivity drift TCG_{AV} is the G_T value divided by the temperature range. Deeper and detailed info available is our LEM technical sales offices (www.lem.com).

Offset voltage @ $I_p = 0$ A:

The offset voltage is the output voltage when the primary current is zero. The ideal value of V_O is $U_C/2$. So, the difference of $V_O - U_C/2$ is called the total offset voltage error. This offset error can be attributed to the electrical offset (due to the resolution of the ASIC quiescent voltage trimming), the magnetic offset, the thermal drift and the thermal hysteresis. Deeper and detailed info available is our LEM technical sales offices (www.lem.com).

Environmental test specifications:

Refer to LEM GROUP test plan laboratory CO.11.11.515.0 with "Tracking_Test Plan_Auto" sheet.
